Dependence Risk

Quantile Regression in Risk Calibration $\square$

## Risk Calibration and Quantile Regression

$\square$ Quantification via value-at-risk (VaR)/expected shortfall (ES)
$\square$ Quantile VaR: dependence risk?
$\checkmark$ Parametric VaR: Chernozhukov and Umantsev (2001), Engle and Manganelli (2004)
$\square$ Nonparametric VaR: Cai and Wang (2008), Taylor (2008) and Schaumburg (2010)
$\square$ Parametric CoVaR: Adrian and Brunnermeier (2010)(AB)

## Risk Calibration

$\square$ Marginal Expected Shortfall (MES): Acharya et al. (2010)
$\square$ Distressed Insurance Premium (DIP): Huang et al. (2010)

## - Go to details

$\square \mathrm{AB}: X_{j}$ and $X_{i}$ are two asset returns,

$$
\mathrm{P}\left\{X_{j} \leq \operatorname{CoVaR}_{j \mid i}^{\tau} \mid X_{i}=\operatorname{VaR}^{\tau}\left(X_{i}\right), M_{t-1}\right\}=\tau
$$

$\square$ Advantages:

- Cloning property
- Conservative property
- Adaptiveness

## CoVaR Construction (AB)

$X_{j, t}$ and $X_{i, t}$ are two asset returns. Two linear quantile regressions:

$$
\begin{align*}
& X_{i, t}=\alpha_{i}+\gamma_{i}^{\top} M_{t-1}+\varepsilon_{i, t}  \tag{1}\\
& X_{j, t}=\alpha_{j \mid i}+\beta_{j \mid i} X_{i, t}+\gamma_{j \mid i}^{\top} M_{t-1}+\varepsilon_{j, t} \tag{2}
\end{align*}
$$

$M_{t}$ : state variables. $F_{\varepsilon_{i, t}}^{-1}\left(\tau \mid M_{t-1}\right)=0$ and $F_{\varepsilon_{j, t}}^{-1}\left(\tau \mid M_{t-1}, X_{i, t}\right)=0$.

$$
\begin{aligned}
\widehat{\operatorname{VaR}}_{i, t} & =\hat{\alpha}_{i}+\hat{\gamma}_{i}^{\top} M_{t-1} \\
\widehat{\operatorname{CoVaR}}_{j \mid i, t} & =\hat{\alpha}_{j \mid i}+\hat{\beta}_{j \mid i} \widehat{V a R}_{i, t}+\hat{\gamma}_{j \mid i}^{\top} M_{t-1}
\end{aligned}
$$

## CoVaR Construction Linear?

Figure 1: Goldman Sachs (GS) and Citigroup (C) weekly returns 0.05 (left) and 0.1 (right) quantile functions. $y$-axis $=G S$ returns; $x$-axis $=C$ returns. LLQR lines. Linear quantile regression line. $95 \%$ Confidence band. $N=$ 546. Data weekly returns 20050131-20100131.

## Nonlinear Dependence

Figure 2: Lehman Brothers (LB) and C weekly returns 0.05 (left) and 0.1 (right) quantile functions. $y$-axis $=\mathrm{LB}$ returns; x -axis $=\mathrm{C}$ returns. LLQR lines. Linear quantile regression line. $95 \%$ Confidence band. $N=546$. Data weekly returns 20050131-20100131.
Quantile Regression in Risk Calibration $\square$

## Nonlinear Dependence

Figure 3: Bank of America (BOA) and $C$ weekly returns 0.05 (left) and 0.1 (right) quantile functions. $y$-axis $=B O A$ returns; $x$-axis $=C$ returns. LLQR lines. Linear quantile regression line. 95\% Confidence band.. $N=546$. Data weekly returns 20050131-20100131.

Quantile Regression in Risk Calibration $\square$

## General Specification

$\square$ Nonparametric quantile regression:

$$
\begin{align*}
X_{i, t} & =f\left(M_{t-1}\right)+\varepsilon_{i, t}  \tag{3}\\
X_{j, t} & =g\left(X_{i, t}, M_{t-1}\right)+\varepsilon_{j, t} \tag{4}
\end{align*}
$$

$M_{t}$ : state variables. $F_{\varepsilon_{i, t}}^{-1}\left(\tau \mid M_{t-1}\right)=0$ and $F_{\varepsilon_{j, t}}^{-1}\left(\tau \mid M_{t-1}, X_{i, t}\right)=0$.
$\square$ Challenges

- The curse of dimensionality for $f, g$
- Numerical Calibration of (3) and (4)

## Research Questions

$\checkmark$ Measure CoVaR in a nonparametric (semiparametric) way
$\square$ Test the performance of the CoVaR
$\square$ What can one learn from the semiparametric specification?
$\square$ Consequences for econometrical modelling?

## Outline

1. Motivation $\checkmark$
2. Locally Linear Quantile Regression
3. A Semiparametric Model
4. Empirical CoVaR
5. Backtesting
6. Conclusions and Outlook

## Locally Linear Quantile Estimation (LLQR)

$\square\left\{\left(X_{i}, Y_{i}\right)\right\}_{i=1}^{n} \subset \mathbb{R}^{2}$ i.i.d. bivariate random variables, locally linear kernel quantile estimator estimated as $\hat{l}\left(x_{0}\right)=\hat{a}_{0,0}$ :

$$
\begin{equation*}
\underset{\left\{a_{0,0}, a_{0,1}\right\}}{\operatorname{argmin}} \sum_{i=1}^{N} K\left(\frac{x_{i}-x_{0}}{h}\right) \rho_{\tau}\left\{y_{i}-a_{0,0}-a_{0,1}\left(x_{i}-x_{0}\right)\right\} . \tag{5}
\end{equation*}
$$

$\square$ Choice of Bandwidth: Yu and Jones (1998):

$$
h_{\tau}=h_{\text {mean }}\left[\tau(1-\tau) \varphi\left\{\Phi^{-1}(\tau)\right\}^{-2}\right]^{1 / 5}
$$

where $h_{\text {mean }}$ : local mean regression bandwidth.

## Stabilized Estimator

$\square$ Calculate $X_{(i: n)}$ (order statistics), then perform LLQR on $\{i / n\}_{i=1}^{n}$ and corresponding $Y_{(i: n)}$
$\square \hat{l}(x) \hat{f}_{X}^{-1}(x)$ is a consistent estimator for the conditional quantile in the original $X$ space

## Uniform Confidence Band

Theorem (Härdle and Song (2010))
Under regularity conditions,

$$
\begin{aligned}
\mathrm{P}\left[(2 \delta \log n)^{1 / 2}\right. & \left.\left\{\sup _{x \in J} r(x)|\hat{l}(x)-I(x)| / \lambda(K)^{1 / 2}-d_{n}\right\}<z\right] \\
& \rightarrow \exp \{-2 \exp (-z)\},
\end{aligned}
$$

as $n \rightarrow \infty$, where $\hat{l}(\cdot)$ is the solution of (5) and $d_{n}$ is a scaling constant.

## Macroeconomic Drivers

Components of $M_{t}$ :

1. VIX
2. Short term liquidity spread
3. Change in the 3 M T-bill rate
4. Change in the slope of the yield curve
5. Change in the credit spread between 10 years BAA-rated bonds and the T-bond rate
6. S\&P500 returns
7. Dow Jones U.S. Real Estate index returns

Change in yields of 3 mon. TB

Figure 4: GS daily returns given 7 market variables and LLQR curves. Data 20060804-20110804. $n=1260 . \tau=0.05$.

Quantile Regression in Risk Calibration $\square$

Figure 5: GS daily returns given 7 market variables and LLQR curves. Data 20060804-20110804. $n=1260 . \tau=0.05$.
Quantile Regression in Risk Calibration $\square$

## A Semiparametric Model

## Partial Linear Model (PLM)

$\square$ The linearity observation (Figure 4,5) implies:

$$
\begin{align*}
& X_{i, t}=\alpha_{i}+\gamma_{i}^{\top} M_{t-1}+\varepsilon_{i, t} \\
& X_{j, t}=\tilde{\alpha}_{j \mid i}+\tilde{\beta}_{j \mid i}^{\top} M_{t-1}+l_{j \mid i}\left(X_{i, t}\right)+\varepsilon_{j, t} \tag{6}
\end{align*}
$$

$I$ : a general function. $M_{t}$ : state variables. $F_{\varepsilon_{i, t}}^{-1}\left(\tau \mid M_{t-1}\right)=0$ and $F_{\varepsilon_{j, t}}^{-1}\left(\tau \mid M_{t-1}, X_{i, t}\right)=0$.
$\square$ Advantages

- Capturing nonlinear asset dependence
- Avoid curse of dimensionality

Figure 6: The nonparametric element of the PLM. $y$-axis=GS daily returns after filtering $M_{t}$ 's effect. $x$-axis=C daily returns. The LLQR quantile curve. Linear parametric quantile line. $95 \%$ Confidence band. Data 20080625-20081223. $\mathrm{n}=126$ (window size). $h=0.2003 . \tau=0.05$.

## Estimation of Partial Linear Model

$\square$ PLM model: Liang, Härdle and Carroll (1999) and Härdle, Ritov and Song (2011)

$$
Y_{t}=\alpha+\beta^{\top} M_{t-1}+I\left(X_{t}\right)+\varepsilon_{t}
$$

$\square$ Consider $[0,1]$ (standard rank space). Dividing $[0,1]$ into $a_{n}$ equally divided subintervals, $a_{n} \uparrow \infty$. On each subinterval, $I(\cdot)$ is roughly constant.

## Estimation of PLM QR

Procedure:

1. Linear element $\beta$ :
$\hat{\beta}=$
$\underset{\beta}{\operatorname{argmin}} \min _{I_{1}, \ldots, I_{a n}} \sum_{t=1}^{n} \rho_{\tau}\left\{Y_{t}-\alpha-\beta^{\top} M_{t-1}-\sum_{m=1}^{a_{n}} I_{m} \mathbf{1}\left(X_{t} \in I_{n t}\right)\right\} ;$
2. Nonlinear element $I(\cdot)$ : With data $\left\{\left(X_{t}, Y_{t}-\hat{\alpha}-\hat{\beta}^{\top} M_{t-1}\right)\right\}_{t=1}^{n}$, applying LLQR.

## Empirical CoVaR

$\square j$ : GS daily returns,
$i$ : C daily returns
Window Size: 126 days (half a year)
Data 20060804-20110804
$\square$ Three types of VaR (CoVaR):

- VaR
- $\mathrm{CoVaR}^{A B}$
- CoVaR ${ }^{P L M}$

Figure 7: CoVaR of $G S$ given the $\operatorname{VaR}$ of $C$. The $x$-axis is time. The $y$-axis is the GS daily returns. PLM CoVaR . AB (2010) CoVaR . The linear QR VaR of GS. Quantile Regression in Risk Calibration

## Empirical CoVaR

Figure 8: CoVaR of GS given the VaR of C during 20080804-20090804. The x-axis is time. The y-axis is the GS daily returns. PLM CoVaR. AB (2010) CoVaR. The VaR of GS.

Quantile Regression in Risk Calibration $\square$

## Backtesting Procedure

$\checkmark$ Berkowitz, Christoffersen and Pelletier (2011): If the VaR calibration is correct, violations

$$
I_{t}= \begin{cases}1, & \text { if } X_{i}<\left(\widehat{\operatorname{Co}) V a} R_{t-1}^{\tau}\left(X_{i}\right)\right. \\ 0, & \text { otherwise }\end{cases}
$$

should form a sequence of martingale difference

Figure 9: The timings of violations $\left\{t: I_{t}=1\right\}$. The circles are the violations of the $\widehat{C o V a R}{ }_{G S \mid C, t}^{P L M}$, totally 95 violations. The squares are the violations of $\widehat{\operatorname{CoVaR}}{ }_{G S \mid C, t}^{A B}$, totally 98 violations. The stars are the violations of $\widehat{V a R}_{G S, t}$, totally 109 violations. $n=1260$.

## Box Tests

$\boxtimes \hat{\rho}_{k}$ be the estimated autocorrelation of lag $k$ of violation $\left\{I_{t}\right\}$ and $N$ be the length of the time series.
$\square$ Ljung-Box test:

$$
\begin{equation*}
\mathrm{LB}(m)=N(N+2) \sum_{k=1}^{m} \frac{\hat{\rho}_{k}^{2}}{N-k} \tag{7}
\end{equation*}
$$

$\checkmark$ Lobato test:

$$
\begin{equation*}
\mathrm{L}(m)=N \sum_{k=1}^{m} \frac{\hat{\rho}_{k}^{2}}{\hat{v}_{k k}} \tag{8}
\end{equation*}
$$

## CaViaR Test

$\square$ Inspired by Engle and Manganelli (2004)
$\square$ Berkowitz, Christoffersen and Pelletier (2011): CaViaR performs best overall
$\square$ Test procedure:

$$
I_{t}=\alpha+\beta_{1} I_{t-1}+\beta_{2} V_{a} R_{t}+u_{t}
$$

where $V_{a} R_{t}$ can be replaced by $\operatorname{CoVaR}_{t}$ in the case of conditional VaR . The residual $u_{t}$ follows a Logistic distribution.
$\square$ The null hypothesis is $\hat{\beta}_{1}=\hat{\beta}_{2}=0$.

## Summary of Backtesting Procedure

$\square \operatorname{LB}(1)$ : Ljung-Box test of lag 1
$\square$ LB(5): Ljung-Box test of lags 5
$\square \mathrm{L}(1)$ : Lobato test of lag 1
$\square \mathrm{L}(5)$ : Lobato test of lags 5
$\square$ CaViaR-O: CaViaR test, all data 20060804-20110804
$\square$ CaViaR-C: CaViaR test, data 20080804-20090804

Table 1: Goldman Sachs VaR/CoVaR backtesting $p$-values.

| Measure | LB(1) | LB(5) | L(1) | L(5) | CaViaR-O | CaViaR-C |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Panel 1 |  |  |  |  |  |  |
| $\widehat{V a R}_{G S, t}$ | 0.3449 | 0.0253* | 0.3931 | 0.1310 | $<0.0001^{* * *}$ | 0.0024** |
| Panel 2 |  |  |  |  |  |  |
| $\widehat{\mathrm{CoVaR}}_{G S \mid S P, t}^{A B}$ | 0.0869 | 0.2059 | 0.2684 | 0.6586 | <0.0001*** | 0.0424* |
| $\widehat{C O V a R}^{P L S M \mid S P, t}$ | 0.0518 | 0.0006*** | 0.0999 | 0.0117* | $<0.0001^{* * *}$ | 0.0019** |
| Panel 3 |  |  |  |  |  |  |
| $\widehat{\operatorname{CoVaR}} A B \mid C, t$ | 0.0489* | 0.2143 | 0.1201 | 0.4335 | $<0.0001^{* * *}$ | 0.0001*** |
| $\widehat{C o V a r ~}^{P L M} \mid C, t$ | 0.8109 | 0.0251* | 0.8162 | 0.2306 | <0.0001*** | 0.0535 |

$*, * *$ and ${ }^{* * *}$ denote significance at the 5,1 and 0.1 percent levels.

## Conclusions and Outlook <br> Conclusions and Outlook

$\checkmark$ Semiparametric PLM does well during financial crisis
$\square$ Nonlinear tail dependence is not negligible
$\square$ Multivariate nonlinear part in PLM

## Macroprudential Risk Measures

$\square$ Marginal Expected Shortfall (MES): Portfolio $R=\sum_{i} w_{i} X_{i}$ where $w_{i}$ : weights, $X_{i}$ : asset return, $0<\tau<1$,

$$
\operatorname{MES}_{\tau}^{i}=\frac{\partial E S^{\tau}(R)}{\partial w_{i}}=-\mathrm{E}\left[X_{i} \mid R \leq-\operatorname{Va}_{\mathrm{R}} R_{R}^{\tau}\right]
$$

$\square$ Distressed Insurance Premium (DIP): Huang et al. (2010) $L=\sum_{i=1}^{N} L_{i}$ total loss of a portfolio

$$
D I P=\mathrm{E}^{Q}\left[L \mid L \geq L_{\text {min }}\right]
$$

## Advantages of CoVaR

$\checkmark$ Cloning Property: if dividing $X_{i}$ into several clones, then the value of CoVaR conditioning on the individual large firm does not differ from the one conditioning on one of the clones
$\square$ Conservative Property: CoVaR conditioning on some bad event, the value would be more conservative than VaR
$\square$ Adaptive to the changing market conditions

## Nonlinear Dependence

Figure 10: BOA and GS weekly returns 0.05 (left) and 0.1 (right) quantile functions. $y$-axis=BOA returns; $x$-axis=GS returns. LLQR lines. Linear parametric quantile regression line. $95 \%$ Confidence band. $N=546$.

## Nonlinear Dependence

Figure 11: LB and AIG weekly returns 0.05 (left) and 0.1 (right) quantile functions. $y$-axis=LB returns; $x$-axis=AIG returns. LLQR lines. Linear parametric quantile regression line. $95 \%$ Confidence band. $N=546$.
